iPSC Strategies to Reduce Time and Cost in Disease Modeling

This work describes the establishment of an optimized iPSC-derived neuronal differentiation platform to streamline disease modeling for ASO screening. By utilizing patient-specific iPSCs, this approach offers a scalable, robust, and cost-effective solution for high-throughput ASO screening, significantly reducing timelines and costs in the preclinical discovery pipeline.

Craig McIntosh, Ph.D.

Associate Director, ASO Discovery, n-Lorem

Hosted by:

Biogen

Introduction

Efficient antisense oligonucleotide (ASO) discovery screening is critical to any drug discovery program, and this is especially true for n-of-1 (nano-rare) therapeutic development. At n-Lorem, this process **must be both cost-effective and time-efficient** to meet the urgent **needs of our patients**.

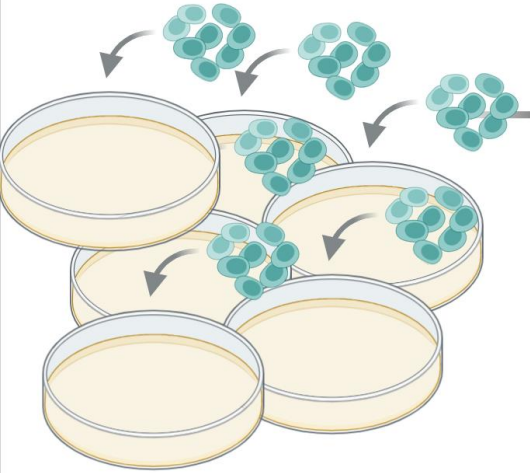
For certain central nervous system (CNS) indications, screening requires the use of **mature neurons** because the target gene is only expressed at this stage of neuronal development.

Traditional Organizations

n-Lorem and other biotech organizations have relied on **Sendai virus–mediated differentiation** of induced pluripotent stem cells (iPSCs) to generate these neurons. However, this approach presents significant challenges

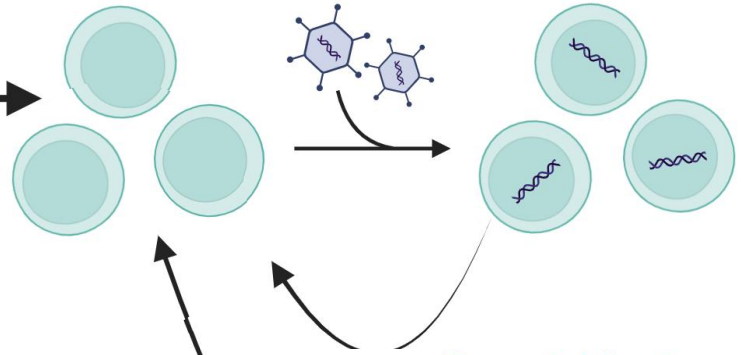
- **Extended generation timelines (up to 8 months)**
- **High cost (~USD 3,000 per ASO plate)**
- **Labor-intensive workflows**
- **Variable neuronal yields**
- **Need for multiple rounds of neuron generation**
- **Limited scalability for high-throughput screening**

1 *Significant iPSC Plating Event*



Sendai Virus (SeV) Transduction

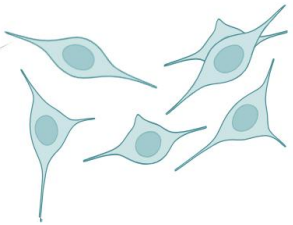
2 *SeV very sensitive to stress*



Initial differentiation

3 *DIV3 split determines neuron yield*

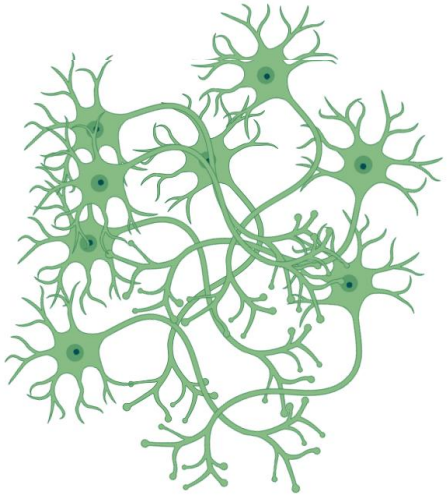
(extremely variable)



Repeatable steps often required - depending on yield

4

Neurons ready for use



Differentiation into mature neurons

Methodology

NGN2 (Neurogenin-2), is a proneural transcription factor that drives **rapid differentiation** of pluripotent stem cells into neurons. We package the NGN2 plasmid using a high-titer lentiviral packaging service. NGN2 is a:

- **Master regulator of neurogenesis**
- **Fast and reproducible neuronal induction**
- **Generates cortical-like neurons**
- **Scalable for disease modeling and screening**

iPSCs

Generation of NGN2 iPSCs

Timeline : 6 to 8 weeks

NPCs

Large scale NPC generation and banking

Timeline : 1.5 weeks

nL00713: ~**250 Millions** (140 Mil, **1.8x**)
nL01121: ~**600 Millions** (160 Mil, **3.75x**)
nL00314: ~**325 Millions** (165 Mil, **2x**)
nL01505: ~**300 Millions** (155 Mil, **2x**)
nL00645: ~**300 Millions** (25Mil, **6X**)

Neurons

Small scale, single dose and dose response screening in neurons

Timeline:
Small scale diff: **4 weeks**
Single dose and DRC: **9 weeks**

Timeline for neuronal screens (good quality iPSCs to end of screening)
21 -23 weeks (5.25 – 6 months)

6

NGN2 differentiated neurons are required to uptake ASOs in a similar manner to Sendai virus method. Control ASOs were dosed via free uptake for 5 days and compared to previously generated Sendai data

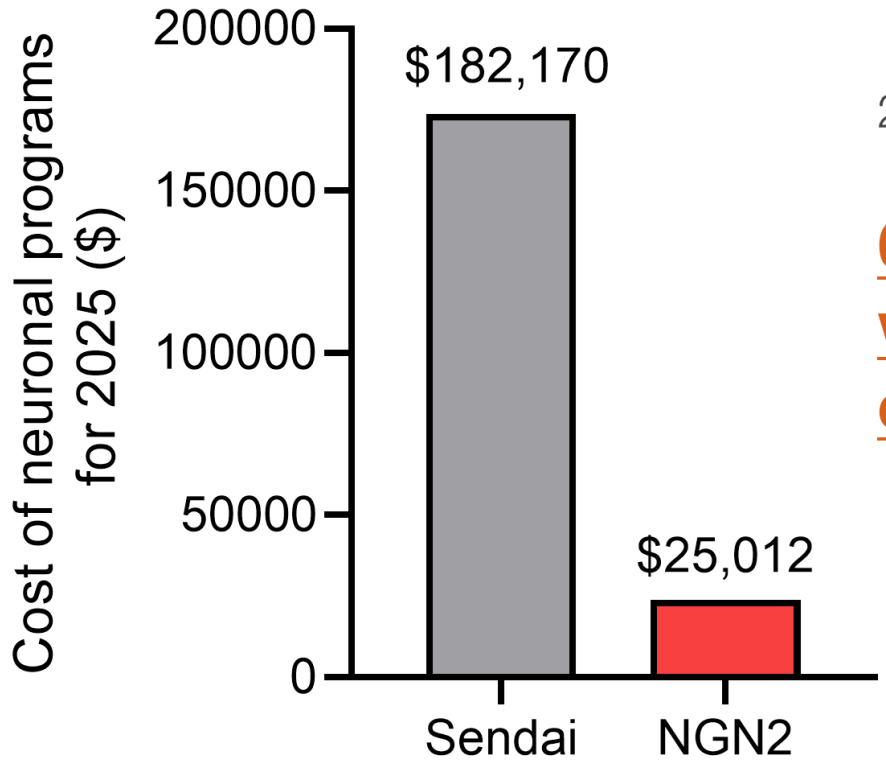
Savings of **$91,370.34**

Conclusion

All the described methodology encompasses a **continuous, diligent and data-driven attempt to optimize** our processes to help more **NANO-RARE PATIENTS TODAY**

Conclusion



2025 Savings: **$157,157**

6.28 x more patients we can help for cost equivalent

Acknowledgements

We would like to thank the **Yeo Lab** at **UCSD** for a portion of the initial NGN2 plasmids provided at the beginning of the study. As well as the **Gleeson Lab UCSD/Rady** for a modified protocol of the current NGN2 presented.

Thank you
